

# COEN 379 HW 4

1.  $h_a(x) = (ax \bmod p) \bmod m$

Following the universal hashing property proof we did in class:

Suppose  $h_a(x_1)$  and  $h_a(x_2)$  are the same

Then,  $r = ax_1 \neq ax_2 = s \pmod{p}$  because  $p$  is prime,  $a \neq 0$  and  $x_1 \neq x_2$

Thus, there are at most  $p-1/m$  values  $s \bmod p$  such that  $r = s \pmod{m}$

But  $r \neq s \bmod p$

So, the probability of such a collision is at most  $p(p-1)/m/(p-1) = p/m$ , which is greater than  $1/m$ , not following the universal property.

2. Using the proof we did in class that we did in order to find the expected total number of horizontal moves of a fair coin, we can apply the same logic to find the expected total number of horizontal moves for a coin with any probability  $p$ .

$$\begin{aligned} E[L] &= E[\text{Sum}(i \geq 0) L_i] = \text{Sum}(i \geq 0) E[L_i] \\ &= \text{Sum}(i=0 \text{ to } i=\log_{1/p}(n)) E[L_i] + \text{Sum}(i \geq 1+\log_{1/p}(n)) E[L_i] \end{aligned}$$

Here,  $E[L_i]$ , or the expected number of horizontal moves on level  $i$  is the geometric random variable counting the number of heads before a tails is observed, which is  $1/p$  in this case.

$$\leq \text{Sum}(i=0 \text{ to } i=\log_{1/p}(n)) 1/p + \text{Sum}(i \geq 1+\log_{1/p}(n)) E[S_i]$$

Here,  $E[S_i]$  is the expected size of the level- $i$  list, which is  $\text{Sum}(j=0 \text{ to } n) p^j = np^i$

$$= 1/p * (1 + \log_{1/p}(n)) + \text{Sum}(i \geq 1+\log_{1/p}(n)) np^i$$

$$np^{(1+\log_{1/p}(n))} = n(p^{*1/n}) = p$$

$$np^{(2+\log_{1/p}(n))} = n(p^{*2*1/n}) = p^2$$

...

$$np^{(n+\log_{1/p}(n))} = n(p^{*n*1/n}) = p^n$$

...

$$= 1/p + (1/p)*\log_{1/p}(n) + \text{Sum}(i \geq 1)p^i$$

Here, we can generalize  $1/p$  and  $\text{Sum}(i \geq 1)p^i$  both to be  $O(1)$  since  $0 < p < 1$

Thus,

$$E[L] \leq (1/p)*\log_{1/p}(n) + O(1)$$

Now, let's see for what value of  $p$  this expression is minimized with examples:

$$E[L] = 1/(0.1)*\log_{1/0.1}(n) + O(1)$$

$$\leq 10 \cdot \log_{10}(n) + O(1)$$

vs.

$$E[L] = 1/(0.9) \cdot \log_{1/0.9}(n) + O(1)$$

$$\leq 1.11 \cdot \log_{1.11}(n) + O(1)$$

Here, the top value is much significantly lower than the bottom value, demonstrating that a lower value of  $p$  leads to an overall lower value. Thus, the expression is minimized when  $p$  approaches 0
